TITLE : A New Variant of the Determination of Melting Point of Fats

ORIG. PUB. : Rev. ind. aliment. prod. animale, 1958, No 9, 31

ABSTRACT : The principle of the method is determination of the temperature of beginning and termination of melting of the fat (F). Into a test tube are placed 4 ml water to which are added 1 drop of 3% aqueous solution of KMnO_4 and 4-6 drops of 1% alcohol solution of phenolphthalein. The bulb of the thermometer is coated, by repeated dipping in molten fat, with a layer 1-2 mm thick, after which the thermometer with the solidified fat is placed into the test tube (the bulb of the thermometer is not allowed to contact the solution), which is inserted into a 1 liter flask with warm water. The first drop of F flowing off the thermometer decolorizes the solution. Temperatures are noted at which

TITLE	Germanium Belometers with little Inertia (Russian).	
PERIODICAL	Zhurnal Tekhn.Fiz., 1957, Vol 27, Nr 1, pp 213-215 (U.S.S.R.)	
ABSTRACT	<p>Received 2/1957 Reviewed 3/1957</p> <p>In the course of the last ten years a considerable number of works on semi-conductor-belometers was published. The sensitive layers of all these belometers were obtained by means of roasting different combinations of oxydes of certain metals (Mn, Ni, Co). The technology of the production of such samples is complicated and makes possible the production of films of a minimum thickness of the order of magnitude of 10 microns. However, for the production of belometers of little inertia films of a thickness of 1 micron or even less would be useful. The easiest method for the production of thin layers is vaporization in the vacuum, especially in the case of elementary materials. The authors used this method for the production of a belometer with a sensitive layer of germanium. Germanium can easily be vaporized in the vacuum at the temperature of ~ 1200°C and the temperature coefficient of resistance is sufficiently high. Germanium was steamed on to a base of mica having a thickness of 30 micron. Onto the carefully purified surface 30 pairs of silver contacts were steamed on in the vacuum by means of a stencil. Next, 30 germanium layers were sprayed through another stencil. The steaming on of the germanium took 10 to 20 minutes, and immediately after the spraying the germanium films were covered with polystyrene lac. The mica plate was then cut into</p>	

Card 1/2

PA - 2188

Germanium Belometers with little Inertia.

30 parts and the individual sensitive elements were then stuck onto bases of copper which warrant the heat transfer necessary for the diminution of the eigen-time. The sensitive element was finally carefully shut off hermetically. The sensitive spot had the size of 1×1 mm and the thickness of 1 to 3 microns, its resistance amounted to 1 - 3 mOhm. Temperature coefficient of the resistance of the sensitive layer was $25 \cdot 10^{-3}$ degree $^{-1}$. The main characteristics of the belometer were measured at the feed voltage of 160 V. The signal was taken from a load resistance connected in a series with the belometer. A black body heated to 100°C served as radiation source and the radiation flux was modulated sinusoidally. At a modulation frequency of 30 c the sensitivity of the belometer was 60-70 Watt (Sensitivity means the ratio between the amplitude of the signal in volts and the amplitude of the variable component of the flux of radiation in Watts). Finally, the noise and the eigentime of the belometers are given. The main advantage of germanium compared with oxide semi-conductors is the possibility of producing very thin layers (of an order of magnitude of one micron and less).

Resp. Ed.: A.F. Ioffe; Tech. Ed.: R.S. Pevzner.

PURPOSE: This collection of articles is intended for scientists, engineers and technicians.

COVERAGE: The collection, published by the Semiconductor Institute, Academy of Sciences, USSR, under the supervision of Academician A.F. Ioffe, contains Parts II and III of a two-volume work on semiconductors. Part II completes the material on semiconductor devices, begun in Volume I, and Part III describes various semiconductor materials. Lack of space did not permit inclusion of such subjects as crystal counters, thermoelectric generators, atomic batteries, luminophores, semiconductor catalyzers, materials for complex cathodes and various other applications of semiconductors. Ioffe points out that the article by the American scientists W. Johnson and K. Lark-

Card 1/9

Semiconductors in Science (Cont.)

SOV/1503

Horovitz on semiconductors at low temperatures deals with a subject hardly covered in the Soviet literature. Similarly, the article by the Swiss scientists G. Busch and U. Winkler fills a gap in the Soviet literature on methods of investigating semiconductor characteristics. These subjects will be dealt with exclusively in a proposed third volume. References appear separately after each article.

SOV.1503

Ch. 15. Ilisavskiy, Yu.V. Avalanche Transistors

75

The author discusses the effects of a strong electric field in semiconductor crystals. He then analyzes the behavior of p-n junctions in germanium and silicon with a large reverse bias and explains the dependence of investigated phenomena on temperature and the effects of various defects in the junction structure. The author also investigates processes occurring in the collector junction of avalanche transistors. In the last chapter he presents a general characteristic of the triode and summarizes the existing presentations of physical processes occurring in these devices which result in the generation of high-frequency oscillations. He presents basic schematic diagrams and examples of avalanche transistor application. In conclusion, he compares these transistors with other devices of this type, and suggests that since they do not possess the several disadvantages characteristic of other devices displaying negative resistance, avalanche transistors may in the future replace thyratrons. There are 46 references, of which 23 are Soviet and 23 English.

TITLE: Current-Voltage Characteristics of a Point Contact Between a Metal and AlSb (Vol'tampernaya kharakteristika tochechnogo kontakta metall-AlSb)

PERIODICAL: Zhurnal Tekhnicheskoy Fiziki, 1958, Vol. 28, Nr 5, pp. 965-973 (USSR)

ABSTRACT: From a practical point of view the interest for AlSb is caused by the fact, that the point contact between a metal and AlSb exhibits rectifier properties and that its forbidden zone (1,5 - 1,65 eV) is considerably wider than that of silicon. This gives rise to the hope, that the application of diodes on a basis of AlSb will considerably increase the maximum temperature limit of the effective operation of semiconductor diodes. In spite of the great practical importance of this problem only very few papers have been devoted to an investigation of AlSb (References 1 - 18). They practically never passed the preparatory stage. In the present paper the author dealt with the further investigation of current-voltage characteristics

Card 1/3

Current-Voltage Characteristics of a Point Contact
Between a Metal and AlSb

57-28-5-8/36

of the point contact between metal and AlSb (of the p- and n-type). He investigated the possibility of a contact formation at a passage of a strong d. c., the temperature dependence of the passage and the inverse current as well as the shape of the static and the pulse-contact characteristics in a strong field. The results of the investigation show, that none of the usual simple models of rectification could be applied to the investigated samples of AlSb. Because of the strong dependence of the inverse current (the height of the contact barrier is between $V_D = 0.30 \div 0.35$ V) the rectification coefficient of the investigated diodes markedly decreases with temperature, and reduces the temperature limit of the effective operation of the diodes. The passage of strong d. c. leads to a considerable increase of the rectification coefficient of the diodes at $V_{exp} = 20 \div 30$ V. It was shown, that a non-rectifying contact between metal and AlSb can be obtained because of a breakdown of the rectification barrier. This circumstance leads to the

Card 2/3

Current-Voltage Characteristics of a Point Contact
Between a Metal and AlSb

97-28-5-8/36

assumption, that the field of application of a probe method can be considerably extended in the investigation of the effect of the strong field. It was discovered, that in p-AlSb deviations from Ohm's law were observed starting from a voltage of from 10-12 V. In this instance, the dependence of the current upon voltage approaches the function $I \sim V^{1/2}$. This proves data on the existence of deep impurities in p - AlSb. The author expresses his gratitude to V. P. Zhuze for valuable help and A. R. Regel' and G. Ye. Pinkus for valuable suggestions. A certain number of measurements were conducted by the student Ye. V. Goncharova of Leningrad State University. There are 8 figures, 2 tables and 20 references, 6 of which are Soviet.

TITLE: Elastic constants of Bi_2Te_3 at 300°K

PERIODICAL: Fizika tverdogo tela, v. 3, no. 11, 1961, 3555-3556

TEXT: The values of the 6 components of the elasticity tensor c_{11} , c_{12} , c_{13} , c_{14} , c_{33} , c_{44} of Bi_2Te_3 are still unknown. The author determined four of these components in monocrystalline samples ($20 \cdot 10^{-3} \text{ mm}^3$) in the natural orientation by means of an УЗМС-7 (UZIS-7) measurement arrangement described by A. G. Ostroumov (P'yezoelektriki, str. 23, 1956) with an oil film being used as acoustic contact agent for the longitudinal measurements, and colophony dissolved in acetone for the transverse measurements. The sound velocity in the arrangement described by Ostroumov was computed from the delay of supersonic pulses (1.67 Mc) in the sample and in a standard solution (15.62% of ethyl alcohol in water). To avoid zero errors the authors used a fused quartz glass standard whose sound velocity values were

AUTHOR:

Ilisavskiy, Yu. V.

TITLE:

The effect of uniaxial deformation on the electrical conductivity of bismuth tellurides and selenides

PERIODICAL: Fizika tverdogo tela, v. 4, no. 3, 1962, 818 - 820

TEXT: According to the multi-ellipsoid model proposed by J. R. Drabble (see below) for the carrier energy spectrum of Bi_2Te_3 deformation of the crystal should not cause any change in conductivity in a direction perpendicular to its slip plane; i. e., $\pi_{33} = \pi_{31} = \pi_{13} = 0$ (2). The correctness of this statement was checked by examining the effect of the piezo-resistance in the slip planes of n-type and p-type Bi_2Te_3 single crystals. For p-type Bi_2Te_3 it was not found possible to determine any exact values of π_{33} as cracks arose. The mechanically stronger n-type Bi_2Te_3 gave well reproducible values at $T = 300^\circ\text{K}$: $\pi_{33} \cdot 10^{12} \text{ cm}^2/\text{dyne} = +118$;

Card 1/3

S/181/62/004/003/042/045
B101/B102

The effect of uniaxial deformation...

+115; +90 (three different samples). For κ_{31} the values were about +170 in p-type Bi_2Te_3 and about -70 in n-type Bi_2Te_3 over a wide temperature range (78 - 300°K) they were fairly constant. Thus Eq. (2) is not satisfied, neither for p-type nor n-type Bi_2Te_3 so that Drabble's model calls for revision. For Bi_2Se_3 , measurements were made of κ_{11} (in the slip plane). At 78 - 300°K, κ_{11} did not exceed $-(2-5) \cdot 10^{-12} \text{ cm}^2/\text{dyne}$.

The question as to whether this low value should be ascribed to the simple shape of the bands or to the very slight anisotropy of the isoenergetic surfaces can be settled only by investigating the piezoelectric and magnetic resistances of n-type Bi_2Se_3 specimens with lower carrier concentrations. There are 2 figures and 11 references: 4 Soviet and 7 non-Soviet. The four most recent references to English-language publications read as follows: T. J. Diesel, L. Hollander, Bull. Am. Phys. Soc., 6, 312, 1961; J. R. Drabble, Proc. Phys. Soc., 72, 380, 1958; M. Pollak, Phys. Rev., 2, 798, 1958; K. Hashimoto, Mem. Fac. Science, Kyusyu Univ., ser. B, 2, 141, 1958.

TITLE: Separation and purification of unsaturated hydrocarbons by extractive distillation

SOURCE: strol si gaze, v. 16, no. 10, 1965, 576-578

TOPIC TAGS: hydrocarbon, fractional distillation, chemical separation, petroleum refining

ABSTRACT: The authors describe the design and operation of a pilot plant for the study of extractive distillation. The plant carries out the separation of olefin and diene C₅ hydrocarbons, with the final phase of the purification consisting of fractional distillation. Orig. art. has: 2 figures. [JPRS]

TITLE: Apparatus for Determining the Thickness of Protective Layers by the Nondestructive Method.

PERIODICAL: Studii și Cercetări de Mecanică Aplicată, 1950, No. 3, pp. 785-792

TEXT: During the last few years the coating of metal surfaces with a protecting layer was considerably developed. The thickness of this layer is determined either by the destructive or by the non-destructive method. Brief reference is made to these two methods. The Institutul de mecanică aplicată (Institute of Applied Mechanics) studied the problem of the nondestructive method and developed an apparatus based on the electric-inductive system. The principle of this system is based on the dependence character between the thickness δ of the layer and the current I , and the flux Φ respectively, represented by the law of the magnetic circuit, in case of a ferro-magnetic core, expressed by formula (1). The dependence between the current I and the thickness δ has the shape of the curve shown in Figure 1. The current is measured by a bridge scheme, which compensates the current I_0 and reduces the influence of the voltage variations of the feeding network. Since this assembly can not be balanced

Apparatus for Determining the Thickness of Protective Layers by the Nondestructive Method

by a single variable element, a compensating scheme, consisting of two rectifying bridges was used. The transducer was given the form of a transformer. The apparatus (Fig. 3) consists of: 1) transducer, 2) rectifying bridges, 3) zero-potentiometer, 4) resistance, 5) measuring instrument, 6) potentiometer for the upper limit of the dial. For the calculation of the elements of the assembly, an equivalent scheme (Fig. 4) was used. The values of R_1 , R_3 are identical with and equal to the internal resistance of the rectifying bridge, including the additional resistance (R_1). The apparatus has the following characteristics: size - 180 x 125 x 140 mm; weight - 2 kg; feeding voltage - 110/220 v; operating voltage - $U = 1.5$ v; maximum intensity - $I_{2max} = 100 \mu a$; measuring limits - 0 - 1 mm. The standard curve of the apparatus (Fig. 5) is valid for layers deposited on a steel basis. The positions of 0 and 100 μa of the curve depend on the influence of the material composition of the basic material, on the influence of the thickness of the basic material, on the influence of the surface quality of the basic material, and on the influence of the curvature. These influences can be eliminated by controlling the apparatus between the limits from 0 to 100 μa . The authors finally describe the operation principle of this apparatus.

TITLE: On an oscillographical method of measuring active, reactive and RLC-impedances and admittances

PERIODICAL: Elektrosvyaz', no. 7, 1962, 69 - 71

TEXT: The advantage of the described method is that it permits a direct measurement (with a precision that proves sufficient for practical purposes) both of impedances and their phase angles, and of their active and reactive components. The measuring device is shown schematically in fig. 1. An a-c voltage with a precisely determined frequency is applied to the measured impedance Z_x from the sound-frequency generator SFG. In series with Z_x is connected a much lower standard resistance R_0 . The voltage across R_0 is amplified by the amplifier Ampl, to whose output is connected the phase shifter $R'C'$. Two voltages phase-shifted by $\pi/2$ emerge at the symmetrical output of the phase shifter and are applied to the two inputs of the oscillograph O. A circle whose radius r depends on Z_x :

$$r = KI_{Zx} = K \frac{U_{Zx}}{|Z_x|}$$

AUTHOR: Iliyev, Lyubomir

TITLE: On the impossibility of analytically continuing a power-series

PERIODICAL: Referativnyy zhurnal, Matematika, no. 3, 1962, 23, abstract 3B115. ("Godishnik Sofiysk. un-t. Fiz.-matem. fak." 1957-1958(1959), 52, no. 1, 1-22)

TEXT: The author uses the Szegő method and proves theorems on the impossibility of analytically continuing a power-series (1), the coefficients of which satisfy the conditions $|c_n| = O(n^\alpha)$, α -- real number, or $|c_n| = O(e^{\varphi(n)})$, where $\varphi(x)$ is subject to a number of conditions (Rzh. Mat., 1956, 7310).

We give two theorems:

Theorem 3: Let $c_n = b_n d_n$, $\lim_{n \rightarrow \infty} \frac{b_{n+1}}{b_n} = 1$, $0 < 1 \leq \frac{|b_n|}{n^\alpha} \leq L$, and let d_n assume only a finite number of values $\Delta_1, \Delta_2, \dots, \Delta_k$, with the exception of the sequence $\{d_{n_v}\}$, which has a positive distance from Card 1/2

S/044/62/000/003/014/092
C111/C222

On the impossibility of

the numbers $\Delta_1, \Delta_2, \dots, \Delta_k$, where $n_\nu - n_{\nu-1} \rightarrow \infty$. Then the series (1) cannot be continued beyond the circle of convergence. The finite sequence u_s, u_{s+1}, \dots, u_t is called periodical, if $u_x = u_{x+p}$,

$x \in [s, t - p]$; $\left[\frac{t-s}{p} \right]$ is called the number of periodical groups.

Theorem 6: Let the series (1) have the convergence radius 1, and let there exist an ξ , $0 < \xi < 1$ and an infinite sequence $\{n_k\}$ with the properties:

1) $\lim_{n_\nu \rightarrow \infty} \sqrt[n_\nu]{|c_{n_\nu}|} = 1$; 2) the sequence $c_{n_\nu - k}$, $k=1, \dots, [\xi n_\nu]$ is periodical with at least two periodical groups; 3) the number 1 is not an accumulation point of the set $\frac{c_{n_\nu - k}}{c_{n_\nu}}$, $k=1, 2, \dots, [\xi n_\nu]$, $\nu=1, 2, \dots$.

Then the series (1) cannot be continued beyond the circle of convergence.
